# Master of Puppets

Infrastructure as Code and Configuration Management on an Open Source Budget

Mike Renfro (renfro@tntech.edu)

Tennessee Tech University

2023-04-24

Introduction, Tools Required
Steps Toward Infrastructure as Code
Typical Infrastructure as Code Workflows
Conclusion

What's the Problem, and Why Should I Care?
What Do You Want to Do About It?
For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

## What's the Problem, and Why Should I Care?

1. The number of services we manage is growing faster than our headcount.
2. Manual configuration leads to manual errors and doesn't scale.
3. Some automation artifacts (e.g., golden images or VM templates) may lack reproducibility (often due to uncrecorded manual changes).
4. Local, sandboxed development environments may be preferred to reduce iteration time and risk to production systems.

Introduction, Tools Required | What's the Problem, and Why Should I Care?
Steps Toward Infrastructure as Code | What Do You Want to Do About It?
Typical Infrastructure as Code Workflows | For the Admin Laptop/Desktop
Conclusion | In the Vagrant VMs (and Production Servers)

## The Tradeoffs

Figure 1: XKCD 1205, "Is It Worth the Time?"

Figure 2: XKCD 1319, "Automation"

Figure 3: XKCD 2730, "Code Lifespan"

What's the Problem, and Why Should I Care?
What Do You Want to Do About It?
For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)
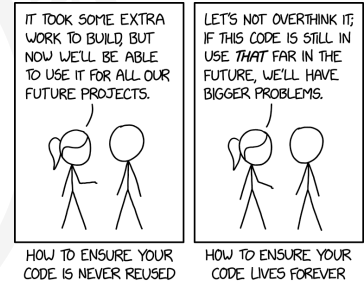

## Minimum Standards for a Viable Infrastructure as Code (IaC) Solution

1. For any given service, define a single source of authority for:
   - installed packages
   - configuration files
   - running services
   - firewall rules
   - etc. with customization allowed for groups of servers.
2. Automatically apply *all* needed changes, but *only* when needed.
3. Maintain balance of consistency and separation of dev/test/prod environments.

4. Automatically maintain records of who made what change when (and ideally, why).
5. Prefer text over binaries (automation for base OS install instead of golden thick image or VM template).
6. Enable developers to test safely and minimize exposure to outside network.

Steps Toward Infrastructure as Code
Typical Infrastructure as Code Workflows
Conclusion

What's the Problem, and Why Should I Care?
What Do You Want to Do About It?
For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

## Stretch Goals for a Viable IaC Solution

1. Allow multiple dev/test environments.
2. Give admins their choice of development platform (Windows, macOS, Linux).
3. Enable management of multiple server OSes (at least multiple Unix, or possibly Windows).
4. Manage endpoints as well as servers.

5. Secure and track secrets (e.g., local database passwords) in central location.
6. Be a good neighbor on already-installed systems (only manage what has to be) and expand scope from there.
7. Avoid vendor lock-in.

For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

# This Isn't the Only Possible Solution

▶ Some tools used here are derived from our production environment.
▶ Other tools are ones I've used or promoted in other projects and contexts.
▶ These tools provide a working reference implementation that's cross-platform (if not totally cross-architecture) with zero purchasing price and open-source licensing.
▶ Replace any of them with other tools matching your local preferences and standards (the concepts are unchanged).

Introduction, Tools Required

For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

# Provisioning (1/2)

Oracle VM VirtualBox *without Extension Pack* (GNU General Public License v2) Type 2 hypervisor for x86 platforms.

▶ Runs on Windows, Linux, and macOS (M1/M2 is in developer preview, and hasn't been tested for this application).

▶ Extension Pack is not open source, and use requires separate license from Oracle.

Introduction, Tools Required

For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

# VirtualBox Less Typical Use for Server Testing

Figure 5: Less Typical Use of VirtualBox on Desktop

Easy? Maybe, but management effort scales with number of virtual machines, and the easy way to get access from your host OS tools (*e.g.*, web browser) either requires manual port forwarding or exposing the VMs to your network.

What Do You Want to Do About It?
For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

# What's Vagrant Doing?

A Vagrant VM is just a VirtualBox VM that:

- ▶ runs in the background (headless)
- ▶ is usually derived from a base installation from https://app.vagrantup.com/
- ▶ configured with a Ruby-syntax Vagrantfile
- ▶ usually supports a shared folder /vagrant mapped from the host OS
- ▶ supports ssh from the host operating system through an automatically-forwarded port (via vagrant ssh)

In the Vagrant VMs (and Production Servers)

## Toolchains

Git (GNU General Public License v2) Keeps track of and logs changes to files in folders. Allows multiple concurrent branches of development, and can push and pull code to/from remote servers (usually via ssh).

Puppet Agent (Apache License) Primarily needed for secret-management tools. Service can be stopped and disabled.

Puppet Development Kit (Apache License) Helper tools for developing and testing Puppet modules and classes.

Introduction, Tools Required
Steps Toward Infrastructure as Code
Typical Infrastructure as Code Workflows
Conclusion

What's the Problem, and Why Should I Care?
What Do You Want to Do About It?
**For the Admin Laptop/Desktop**
In the Vagrant VMs (and Production Servers)

# Editing

Microsoft Visual Studio Code (MIT License) 800 pound gorilla of text editors, `emacs` for a new generation.

Puppet VSCode Extension (Apache License) Provides syntax highlighting, code completion, and linting of Puppet code. Integrates with Puppet Development Kit.

Introduction, Tools Required
Steps Toward Infrastructure as Code
Typical Infrastructure as Code Workflows
Conclusion

What's the Problem, and Why Should I Care?
What Do You Want to Do About It?
For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

## Configuration Management

Puppet (primary server and agent) (Apache License) a tool that helps you manage and automate the configuration of servers.

▶ Code is declarative, describing the desired state of your systems, not the sequence of steps needed to get there.

▶ Puppet primary server stores the code defining your desired state, and compiles it with facts provided by the agent into a catalog.

▶ Puppet agent translates the compiled catalog into host-specific commands and executes them.

▶ Run the agent on the Puppet primary server to have it define its own configuration.

Introduction, Tools Required    What's the Problem, and Why Should I Care?
Steps Toward Infrastructure as Code    What Do You Want to Do About It?
Typical Infrastructure as Code Workflows    For the Admin Laptop/Desktop
Conclusion    In the Vagrant VMs (and Production Servers)

## Version Control Server

Gitea (MIT License) self-hosted Git server, features:

▶ single Go binary with SQLite support.
▶ issue tracking and wikis.
▶ organizational hierarchy.
▶ OpenID Connect single sign-on (yes, it works with Azure Active Directory).
▶ branch protection and review before merge.
▶ webhooks to trigger automation on various events.

What's the Problem, and Why Should I Care?
What Do You Want to Do About It?
For the Admin Laptop/Desktop
In the Vagrant VMs (and Production Servers)

## Continuous Deployment

Adnan Hajdarevic (adnanh)'s Webhook (MIT License) lightweight configurable tool
written in Go, that allows you to easily create HTTP endpoints (hooks) on
your server, which you can use to execute configured commands.

r10k (Apache License) provides a general purpose toolset for deploying Puppet
environments and modules. Maps a branch in a Git repository to a Puppet
environment.

Combining Git branches, Gitea webhooks, adnanh's Webhook, and r10k allows easy
management of multiple Puppet environments for developing and testing services.

Minimum Viable IaC Part 2: Bootstrapping a Puppet Primary Server

## Git

- ▶ Windows, macOS, Linux installation: you should be able to follow Software Carpentry's template workshop instructions for installation.
- ▶ Windows, macOS, Linux setup: following with Software Carpentry's Setting Up Git page, opening a command prompt and running:
  - ▶ `git config --global user.name "Your Name"`
  - ▶ `git config --global user.email "you@yourplace.edu"`
  - ▶ and either:
    - ▶ `git config --global core.autocrlf input` for macOS and Linux, or
    - ▶ `git config --global core.autocrlf false` for Windows

  should be enough to get started.

# How To Make the First Vagrant VM?

We want a VM:

▶ running a Red Hat-family OS, version 8
▶ supporting a shared folder /vagrant mapped from the host OS

Start the definition of a new Vagrant VM in the repository folder with `vagrant init bento/rockylinux-8`, and look at the `Vagrantfile` that was just created.

(The bento Vagrant boxes are built by the Chef Bento project.)

Introduction, Tools Required     Installing and Setting Up the Tools

Typical Infrastructure as Code Workflows     Minimum Viable IaC Part 1: Bootstrapping a Git Server
Conclusion     Minimum Viable IaC Part 2: Bootstrapping a Puppet Primary Server

## The First Vagrantfile (1/2)

Generated from `vagrant init bento/rockylinux-8`, filtered down to interesting commands and comments.

```ruby
Vagrant.configure("2") do |config|
  config.vm.box = "bento/rockylinux-8"
  # config.vm.network "forwarded_port", guest: 80, host: 8080
  # config.vm.network "forwarded_port", guest: 80, host: 8080,
  #   host_ip: "127.0.0.1"
  # config.vm.network "private_network", ip: "192.168.33.10"
  # config.vm.provider "virtualbox" do |vb|
  #   # Customize the amount of memory on the VM:
  #   vb.memory = "1024"
  # end
```

## The First Vagrantfile (2/2)

```
  # config.vm.provision "shell", inline: <<-SHELL
  #   apt-get update
  #   apt-get install -y apache2
  # SHELL
end
```

You'll also see a 1 badge on the Source Control button in Visual Studio Code, indicating there's one pending change in the repository folder (the creation of the Vagrantfile).

Steps Toward Infrastructure as Code      In the Vagrant Development Environment
Typical Infrastructure as Code Workflows      Minimum Viable IaC Part 1: Bootstrapping a Git Server
Conclusion      Minimum Viable IaC Part 2: Bootstrapping a Puppet Primary Server

## Installing a New Vagrant VM with `vagrant up`

- ▶ Running `vagrant up` from the Visual Studio Code terminal builds the VM.
- ▶ Running `vagrant ssh` from the Visual Studio Code terminal results in you being logged into a `vagrant` account in the Linux VM, which has passwordless sudo rights.
- ▶ If you exit back out to your host command prompt, you can do a `vagrant destroy` to shut down and delete the VM.

Once that's working, we'd like to record the new Vagrantfile into version control in Visual Studio Code, but there are complications.

## Setting Up Version Control (How to Ignore Machine-Generated Files)

▶ View / Source Control

Notice there are several other files in the repository folder now (the Source Control button probably has a badge of 3 now). These are from the .vagrant folder that Vagrant uses to track virtual machine information.

▶ Right-click one of the files, select "Add to .gitignore"
▶ Notice the file is absent from the Source Control button, and there's a new file .gitignore.
▶ Go back to the folder view (View / Explorer)
▶ Select the file .gitignore to open it in the editor
▶ Edit the only line in .gitignore to be just .vagrant/ (no filename) and save the file.

Introduction, Tools Required | Installing and Setting Up the Tools

Conclusion | Minimum Viable IaC Part 2: Bootstrapping a Puppet Primary Server

# Setting Up Version Control (Adding and Committing Useful Files)

▶ Notice the Source Control badge now reads 2 (one for `Vagrantfile`, one for `.gitignore`).
▶ Right-click `Vagrantfile`, select "Stage Changes" (or hit + sign to right of `Vagrantfile`).
▶ Repeat for `.gitignore`.
▶ In the "Message" text entry, enter `Define initial Vagrantfile and .gitignore` and select the "Commit" button.

In theory, Git commits should be "atomic", *i.e.*, a single, complete unit of work that can be described in a single sentence. In practice, we're often not that disciplined about it.

Git commit messages should be short and imperative, completing the sentence, "when applied, this commit will . . . ".

# What Would We Like to Change?

## Things to Fix

1. VM hostname is currently `localhost`, would like that to change.
2. Need some actual configuration (packages, config files, services, etc.)
3. Need *multiple* VMs (Git server, Puppet primary server, Puppet client, etc.)
4. Need Puppet agent to poll Puppet primary server for changes (requires name resolution from DNS, host file, etc.)

## Tools for Fixing Things

1. `Vagrantfile` settings
2. VM provisioners (`shell` shown by default, but `puppet` provisioner also available)
3. Provisioners can also read from files (shell scripts, Puppet manifests)
4. Files in the repository folder (show up in `/vagrant` in the VMs)
5. DRY (don't repeat yourself) principle (avoid copy/paste)

## Useful Puppet Resource Types (Most Common in **Bold**)

- ▶ Command execution: **exec**, **cron**
- ▶ File-related: **file**, filebucket, **mount**, tidy
- ▶ Package management: **package**, **yumrepo**
- ▶ SELinux: **selboolean**, selmodule
- ▶ Services: **service**
- ▶ User-related: **group**, **ssh_authorized_key**, **user**
- ▶ Manifest structure: **notify**, resources, schedule, stage

- ▶ Resources are (usually) cross-platform, and are implemented through lower-level *providers* that are OS/platform-specific (*e.g.*, dnf, yum, apt, etc. for packages).
- ▶ Other resource types can be written in Ruby if needed, but it's not often you'll need to write one.

# Final Configuration of Gitea Through the Web

▶ Head to http://10.234.24.2:3000/ in the host browser for initial setup of Gitea.
  ▶ Database Type: SQLite3
  ▶ Gitea Base URL: http://10.234.24.2:3000/
  ▶ Administrator Username: gitadmin
  ▶ Password: (anything)
  ▶ Email Address: (anything)

▶ On the host, generate an ssh key with `ssh-keygen -t ed25519`, then `cat ~/.ssh/id_ed25519.pub` (if you already have an ssh public key, you can cat it instead).

▶ Copy/paste the public key content into http://10.234.24.2:3000/user/settings/keys.

▶ At the host terminal, re-run `vagrant provision git --provision-with puppet` to finalize the last Gitea settings from Puppet.

# Saving a Copy of the Vagrant repository in Gitea

In Gitea web interface:

▶ Create new organization `theits23` to hold repositories.
▶ Create new, uninitialized repository `iac-project` in the `theits23` organization.

In VS Code window:

▶ View / Source Control
▶ "3 dots" button above the commit message box / Remote / Add Remote
▶ URL: `git@10.234.24.2:theits23/iac-project.git`, Name: `origin`
▶ Click the Publish Branch button

Now every time you make a commit, you'll be able to push that commit to the remote repository.

## Minimum Viable IaC Part 2: Bootstrapping a Puppet Primary Server

Repeat the same procedure to make a new Vagrant VM for Puppet. Realistically, a Puppet server needs at least 4 GB RAM, and extra cores don't hurt. Add the following to the `Vagrantfile`, right below the Git server definition:

```
config.vm.define "puppet" do |puppet|
  puppet.vm.provider "virtualbox" do |vb|
    vb.cpus = "2"
    vb.memory = "4096"
  end
  puppet.vm.hostname = "puppet"
  puppet.vm.network "private_network", ip: "10.234.24.3",
    netmask: "255.255.255.0"
end
```

Provisioning a New Web Server in Puppet

## Webhook Between Gitea and Puppet

We want to automatically have changes to a Puppet code repository stored in Gitea automatically show up on the Puppet server.

Gitea can be configured to make a web request when certain events occur on any or all branches in a repository. In our case:

▶ Every change to every branch will trigger a web request to the webhook service on the Puppet server.
▶ The webhook service will be told what branch was changed.
▶ The webhook service will run a defined script with a command parameter including the branch name.
▶ The script will run the r10k program to check out that branch, pull down prewritten modules from Puppet Forge or Git repositories, and deploy an entire Puppet environment defining multiple servers.

# Roles, Profiles, and Component Modules

### The roles and profiles method

▶ A server has one overall role
▶ That role can have things common with servers in other roles, including:
  ▶ security baselines
  ▶ who gets sudo
  ▶ . . .
▶ Those common things are profile classes, include all you want into the role
▶ Profile classes may include other profile classes, and also include component modules
▶ Component modules typically manage one piece of software (Apache, Samba, etc.)
▶ Lots of component modules for various software at Puppet Forge.

Introduction, Tools Required
Steps Toward Infrastructure as Code
Typical Infrastructure as Code Workflows
Conclusion

puppet-control Repository
Webhook Between Gitea and Puppet
GitHub Flow for Managing Development/Testing/Bugfix Environments
Provisioning a New Web Server in Puppet

## Provisioning a New Web Server in Puppet (1/10)

Modify the `Vagrantfile` to include a web server VM:

```
config.vm.define "web" do |web|
  web.vm.hostname = "web"
  web.vm.network "private_network", ip: "10.234.24.4",
    netmask: "255.255.255.0"
end
```

and the Puppet `manifests/default.pp` to include:

```
node 'web.theits23.renf.ro' {
  notify { 'web to be configured from puppet server':
    message => 'Web server to be configured from the Puppet server.',
  }
}
```

Typical Infrastructure as Code Workflows
**Conclusion**

Did We Meet the Goals?
Things We Didn't Get To
Software Credits

# Minimum Standards for a Viable Infrastructure as Code (IaC) Solution

## Puppet covers

1. For any given service, define a single source of authority for packages, configuration files, running services, firewall rules, etc. with customization allowed for groups of servers.
2. Automatically apply *all* needed changes, but *only* when needed.
3. Maintain balance of consistency and separation of dev/test/prod environments.

## Git covers

4. Automatically maintain records of who made what change when (and ideally, why).

## Vagrant (mostly) covers

5. Prefer text over binaries (automation for base OS install instead of golden thick image or VM template).
6. Enable developers to test safely and minimize exposure to outside network.

# Stretch Goals for a Viable IaC Solution

## Puppet covers

1. Allow multiple dev/test environments.
2. Give admins their choice of development platform (Windows, macOS, Linux).
3. Enable management of multiple server OSes (at least multiple Unix, or possibly Windows).
4. Manage endpoints as well as servers.
5. Secure and track secrets (e.g., local database passwords) in central location.
6. Be a good neighbor on already-installed systems (only manage what has to be) and expand scope from there.
7. Avoid vendor lock-in.

# Things We Didn't Get To

- ▶ Cross-platform support in Puppet
- ▶ Running Puppet agent as a service
- ▶ Encrypted data in Hiera
- ▶ Options for separating Hiera data by OS, OS family, domain, etc.
- ▶ Encterprise Node Classifiers to centrally control which nodes get which environment
- ▶ Deeper dive into "facts" gathered by each node that inform the compiled catalog
- ▶ Distributing files and templates from Puppet
- ▶ Adding parameters to profile classes (usually populated from Hiera)
- ▶ Puppet Development Kit for building your own component modules
- ▶ More Gitea settings (branch protection, centralized authentication, . . . )
